# Generating Random WMC Instances <br> An Empirical Analysis with Varying Primal Treewidth 

Paulius Dilkas<br>National University of Singapore, Singapore

CPAIOR 2023

## Which Algorithm Is Better? It Depends on the Data

- DQMR
$\triangle$ Grid
- Mastermind
+ Non-binary
® Other binary
* Random Blocks

The runtime data is from Dilkas and Belle (2021): various Bayesian networks encoded using the approach by Darwiche (2002)

## The Problem: Weighted Model Counting (WMC)

- A generalisation of propositional model counting (\#SAT)
- Applications:
- graphical models
- probabilistic programming
- neuro-symbolic AI
- WMC algorithms use:
- dynamic programming
- knowledge compilation

## Example

$$
\begin{aligned}
& w(x)=0.3, w(\neg x)=0.7 \\
& w(y)=0.2, w(\neg y)=0.8
\end{aligned}
$$

$$
\begin{aligned}
& \text { WMC }(x \vee y)=w(x) w(y)+ \\
& w(x) w(\neg y)+w(\neg x) w(y)=0.44
\end{aligned}
$$

- SAT solvers

## (Some of the) WMC Algorithms

- Cachet (Sang et al. 2004)
- a SAT solver with clause learning and component caching
- C2D (Darwiche 2004)
- knowledge compilation to d-DNNF
- D4 (Lagniez and Marquis 2017)
- knowledge compilation to decision-DNNF
- miniC2D (Oztok and Darwiche 2015)
- knowledge compilation to decision sentential decision diagrams
- DPMC (Dudek, Phan and Vardi 2020)
- dynamic programming with algebraic decision diagrams and tree decomposition based planning

## Tree Decompositions and Primal Treewidth

Formula in CNF:

$$
\phi=\left(x_{4} \vee \neg x_{3} \vee x_{1}\right) \wedge\left(\neg x_{2} \vee x_{4}\right) \wedge\left(\neg x_{1} \vee x_{2} \vee x_{4}\right)
$$

## Tree Decompositions and Primal Treewidth

Formula in CNF:

$$
\phi=\left(x_{4} \vee \neg x_{3} \vee x_{1}\right) \wedge\left(\neg x_{2} \vee x_{4}\right) \wedge\left(\neg x_{1} \vee x_{2} \vee x_{4}\right)
$$

Its primal graph:

## Tree Decompositions and Primal Treewidth

Formula in CNF:

$$
\phi=\left(x_{4} \vee \neg x_{3} \vee x_{1}\right) \wedge\left(\neg x_{2} \vee x_{4}\right) \wedge\left(\neg x_{1} \vee x_{2} \vee x_{4}\right)
$$

Its primal graph:

Its minimum-width tree decomposition:

## Tree Decompositions and Primal Treewidth

Formula in CNF:

$$
\phi=\left(x_{4} \vee \neg x_{3} \vee x_{1}\right) \wedge\left(\neg x_{2} \vee x_{4}\right) \wedge\left(\neg x_{1} \vee x_{2} \vee x_{4}\right)
$$

Its primal graph:

Its minimum-width tree decomposition:

$\therefore$ the primal treewidth of $\phi$ is 2

## The Parameterised Complexity of WMC Algorithms

Let $n$ be the number of variables and $m$ be the number of clauses.

- Component caching (used in CACHET) is $2^{\mathcal{O}(w)} n^{\mathcal{O}(1)}$, where $w$ is the branchwidth of the underlying hypergraph (Bacchus, Dalmao and Pitassi 2009)
- Branchwidth is within a constant factor of primal treewidth
- C2D is based on an algorithm, which is $\mathcal{O}\left(2^{w} m w\right)$, where $w$ is at most primal treewidth (Darwiche 2001; Darwiche 2004)
- DPMC can be shown to be $\mathcal{O}\left(4^{w} m n\right)$, where $w$ is an upper bound on primal treewidth

## From Random SAT to Random WMC

We introduce parameter $\rho \in[0,1]$ that biases the probability distribution towards adding variables that would introduce fewer new edges to the primal graph.
Example partially-filled formula:
$\left(\neg x_{5} \vee x_{2} \vee x_{1}\right) \wedge\left(x_{5} \vee ? \vee\right.$ ? $)$

Its primal graph:

| $x_{1}$ | $x_{3}$ |
| :---: | :---: |
| $/{ }_{3}$ |  |
| $x_{2}-x_{5}$ | $x_{4}$ |

## The probability distribution for the next variable

Base probability of each variable being chosen:

$$
\frac{1-\rho}{4} .
$$

Both $x_{1}$ and $x_{2}$ get a bonus probability of $\rho / 2$ for each being the endpoint of one out of the two neighbourhood edges.

The Relationship Between $\rho$ and Primal Treewidth

## Peak Hardness w.r.t. Density

Let $\mu$ denote the density, i.e., the number of clauses divided by the number of variables.

- Cachet is known to peak at $\mu=1.8$ (Sang et al. 2004)
- Bayardo Jr. and Pehoushek (2000) show some \#SAT algorithms to peak at $\mu=1.2$ and $\mu=1.9$

## Peak Hardness w.r.t. Density

Let $\mu$ denote the density, i.e., the number of clauses divided by the number of variables.

- Cachet is known to peak at $\mu=1.8$ (Sang et al. 2004)
- Bayardo Jr. and Pehoushek (2000) show some \#SAT algorithms to peak at $\mu=1.2$ and $\mu=1.9$
- In our experiments:
- DPMC peaks at $\mu=2.2$
- all other algorithms peak at $\mu=1.9$

## Peak Hardness w.r.t. Density (when $\rho=0$ )

## Hardness w.r.t. Primal Treewidth (when $\mu=1.9$ )

## Is The Relationship Exponential?

Let us fit the model $\ln t \sim \alpha w+\beta$, i.e., $t \sim e^{\beta}\left(e^{\alpha}\right)^{w}$, where $t$ is runtime, and $w$ is primal treewidth

## Is The Relationship Exponential?

Let us fit the model $\ln t \sim \alpha w+\beta$, i.e., $t \sim e^{\beta}\left(e^{\alpha}\right)^{w}$, where $t$ is runtime, and $w$ is primal treewidth

| $4.3-$ | 0.62 | 0.33 | 1 | 0.94 | 0.53 |  |

## Is The Relationship Exponential?

Let us fit the model $\ln t \sim \alpha w+\beta$, i.e., $t \sim e^{\beta}\left(e^{\alpha}\right)^{w}$, where $t$ is runtime, and $w$ is primal treewidth

## Does Real Data Confirm Our Observations?

## Bonus: How DPMC Reacts to Redundancy in Weights

Let $\epsilon$ be the proportion of variables $x$ s.t. $w(x)=w(\neg x)=0.5$

## Summary

- This work introduced a random model for WMC instances with a parameter that indirectly controls primal treewidth
- Observations:
- All algorithms scale exponentially w.r.t. primal treewidth
- The running time of DPMC:
- peaks at a higher density
- and scales worse w.r.t. primal treewidth
- Future work:
- A theoretical relationship between $\rho$ and primal treewidth
- Non-k-CNF instances
- Algorithm portfolios for WMC

## Generating Random WMC Instances: The Algorithm

```
\phi\leftarrow empty CNF formula;
G}\leftarrow\mathrm{ empty graph;
for }i\leftarrow1\mathrm{ to }m\mathrm{ dos
~\leftarrow\emptyset;
for }j\leftarrow1\mathrm{ to }k\mathrm{ do&
x\leftarrow newVariable(X,G);
V (G)\leftarrow\mathcal{V}(G)\cup{x};
\mathcal{E}(G)\leftarrow\mathcal{E}(G)\cup{{x,y}|y\inX};
X\leftarrowX\cup{x};
\phi\leftarrow\phi\cup{{I/~~\mathcal{U}{x,\negx}|}|x\inX}};
```

## How to Pick a Variable

Parameter $\rho \in[0,1]$ biases the probability distribution towards adding variables that would introduce fewer new edges.
Function newVariable (set of variables $X$, primal graph $G$ ):
$N \leftarrow\{e \in \mathcal{E}(G)||e \cap X|=1\} ;$
if $N=\emptyset$ then return $x \operatorname{\sim r} \mathcal{U}\left(\left\{x_{1}, x_{2}, \ldots, x_{n}\right\} \backslash X\right)$;
return

$$
x \sin \left(\left\{x_{1}, x_{2}, \ldots, x_{n}\right\} \backslash X, y \mapsto \frac{1-\rho}{n-|X|}+\rho \frac{|\{z \in X \mid\{y, z\} \in \mathcal{E}(G)\}|}{|N|}\right) ;
$$
